

The following list is a result of too many nights racing through Messier marathons, wandering through the Herschel 400, scanning the southern horizon for unexpected treasures, star-hopping for invisible faint fuzzies, and finally, finding myself at the helm of a 22-inch Go-To telescope, not knowing what to look at next! You'll no doubt recognize many of the objects I've included. Many are the finest, most visited, destinations in the night sky. Some are the best in their class, although they may still seem a challenge with apertures under 20 inches. A few will make you yearn for your old 3-inch refractor, or dark skies from your earliest deep sky memories.

The list is compiled in "constellation by right ascension, right ascension within constellation", order. If you use digital setting circles or a driven Go-To telescope, you'll appreciate the "by constellation" tasking. The SkyQ designation rates the objects first by sky quality (naked-eye limiting magnitude 4-5-6+ was what I had in mind, it varies...), and exclamation marks flag objects that are particularly notable. For double and multiple stars, judge your night and your telescope on the Size/Sep column. Remarks are mostly from old notes scribbled at the eyepiece of a 20-inch Dobsonian or a 5-inch richest field refractor. Some notes were culled from other observer's posts, periodicals, and numerous texts. Positional elements for all NGC and IC objects are epoch 2000, stellar positional elements are mixed. Current separations for double stars are estimated for 2000 (some are surprising if you've been observing true binaries for 30 years!) The farthest south object in the list is Alpha Centauri, followed closely by Eta Carina. The dimmest object, and most challenging, would have to be Einstein's Cross at magnitude 17 1/2, followed by the Twin Lensing Quasar in Ursa Major at 16 1/2 (which was pretty easy at the Winter Star Party in my old 20-incher.) All told, of the 400 objects in the list there are 179 galaxies, 59 planetary nebulae, 37 open clusters, 29 globular clusters, 21 diffuse or "bright" nebulae, 4 super nova remnants, and 2 lensed quasars (numerous anecdotal objects are interspersed in the Remarks column.) The remaining 75 stellar objects are double and multiple stars, contrasting color double stars, and a good sampling of the best deep red carbon stars. There are 145 objects listed with a SkyQ of 4, perfect for small telescopes or average nights. On a better than average night you can easily add 170 objects with a SkyQ of 5, and on those truly remarkable deep sky nights, 85 objects with a SkyQ of 6 will test your telescope optics and your observing skills.

If you find I've omitted one of your favorite objects, make a note and send it to me. Similarly, if you feel an object on the list is overrated, I'd like to hear your opinion on that as well. The list is an evolving project, I hope you have as much fun using it as I had creating it.

Vic Menard
